II. CONTENT.....4

 a. Detail Concept.....4

III. CONCLUSION.....4

I. INTRODUCTION

The NTC Group runs a system that covers both cybersecurity and network engineering. This seminar covered how their security and networking teams work to protect and manage enterprise internet services. We learned about the main parts of their daily operations and the tools they use to stop threats.

II. CONTENT

The security operations center is the main defense team. It has different levels of analysts working under a manager and a CTO. They watch the system all day and night to find and fix security problems. They hunt for threats and write compliance reports. These teams stop many kinds of attacks like malware and phishing. They also deal with social engineering and insider threats along with DDoS and zero day attacks. To do this they test different tools. They try SentinelOne and Shuffle. They also look into The Hive, OpenCTI, Fortinet and Wazuh to manage their threat response. The network engineering side manages the connections from global endpoints to the core network. The connection goes through fiber to the home modems to a BRAS router. An aggregation layer sits in the middle separating the private intranet from the public internet. Customers rent network ports through subscriptions to get bandwidth options. The company charges them based on upstream data. All the operation materials and backend infrastructure are kept in the network operations center. They use content delivery networks to store local caches and make performance faster. They also provide web application firewalls to companies and use a transaction dashboard to manage network plan packages. The Data Centre on the other hand is just unbelievably astounding and a new experience for us as students to see.

III. CONCLUSION

The NTC Group shows how network delivery and security must work together. The security analysts use special tools to defend against complex attacks. The engineering team uses routers and local caches to make sure bandwidth is fast and reliable. The main lesson from this seminar is that combining strong security workflows with good network design improves the safety and speed of internet services for customers.
